5. The USPS handwritten digits dataset is a 8-bit grayscale images of "0" through "9". There are 1100 samples of each class/digit. Each image is 16x16 (256 pixels) image.
Image: 16x16 pixels
Number of samples per class = 1100
Total pixels per image/number of features = 16 * 16 = 256
Bits representation = each feature is 8 bits (1 byte)

The multivariate normal distribution is often used as a model for multivariate data.
The multivariate normal distribution uses the following parameters:

> *μ - Mean vector* - The mean vector would consist of the sample mean of pixel values for each digit class. Each element in the mean vector corresponds to a specific pixel in the image.
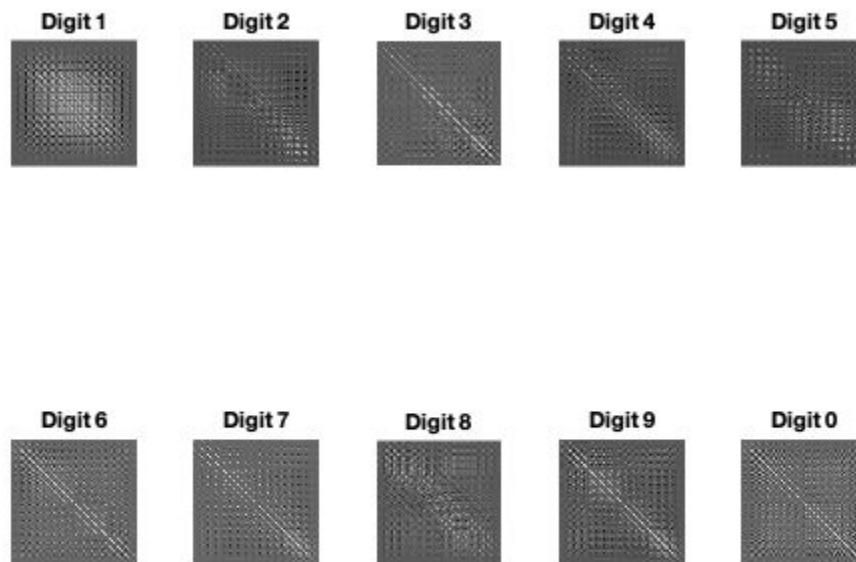

> *Σ - Covariance matrix* - Diagonal elements contain the variances for each variable, and off-diagonal elements contain the covariances between variables. The covariance matrix represents the covariance between pairs of pixel values across the images of a particular digit class. It captures the variability and correlation among pixel values within each digit class.

Estimating the computational cost involves computing the sample mean and covariance matrix for each digit class:

Sample Mean Vector calculation:
- For each digit class, the sample mean is computed by summing the pixel values across all images and dividing by the total number of images.
- Computational Cost: For each class, the cost is proportional to the number of pixels (256 for 16x16 images) multiplied by the number of training points (1100).
- Total operations = total classes/digits * samples per class * number of features/pixels per class = 10 * 1100 * 256
- In total we would have 10 mean vectors (for 10 digits) with 256 elements in each.

Sample Covariance Matrix calculation:
- The sample covariance matrix involves computing the covariance between pairs of pixel values across all images within each digit class.
- Computational Cost: For each class, the cost is proportional to the number of pixels squared (256x256) multiplied by the number of training points (1100).

Total operations = total classes/digits * samples per class * number of features/pixels per class * columns of the covariance matrix = 10 * 1100 * 256 * 256
- In total we would have 10 covariance matrices of size 256x256 each.

The final estimate of the computational cost is approximately 7 billion.
The computational cost of computing the multivariate normal distribution parameters for each digit class scales linearly with the number of classes and the number of training points, and quadratically with the size of individual images.
